

# Introduction to Computer Programming

Instructor: HOU, Fen

2025

# What is a computer?

- ❑ Definition: Device capable of performing computations and making logical decisions.
- ❑ Organization:

# What is a computer?

## ❑ Input unit

- ❑ Obtains information from input devices
- ❑ Keyboard, mouse, microphone, scanner, etc.

## ❑ Output unit

- ❑ Takes information processed by computer, which is used to control other devices
- ❑ Places information on output devices
- ❑ Printer, etc.

## ❑ Central processing unit (CPU)

- ❑ Control unit: supervises and coordinates other sections of computer
- ❑ Arithmetic and logic unit: performs arithmetic calculations and logic decisions

# What is a computer?

- ❑ Memory unit (or primary memory)
  - ❑ Refers to the random access memory(RAM)
  - ❑ Rapid access, relatively low capacity
  - ❑ Retains information from input unit so as to make it immediately available for processing
  - ❑ Retains processed information until placed on output devices
- ❑ Storage unit (or secondary storage unit)
  - ❑ Long-term, high-capacity memory section
  - ❑ Store data and programs that are not immediately needed.
  - ❑ Secondary storage devices such as disks and optical discs
  - ❑ Longer to access than primary memory
  - ❑ Less expensive than primary memory

# Memory Organization

- ❑ In the lowest level, computers understand only 0 and 1.
- ❑ Computer memory stores a sequence of 0 and 1.
- ❑ Each such storage unit is called as a bit.
- ❑ Eight bits are grouped together to form a larger storage unit called a byte.

# Memory Organization

- ❑ Each byte has a unique address for identification
- ❑ Computer memory can thus be viewed as a series of bytes.

# What is a Computer Program?

- ❑ Sets of instructions that tells the computer how to process the data.
- ❑ Writing computer programs means writing sets of instructions in some languages that tell the computer what to do.

# Machine Language 机器语言

- ❑ Only language computer directly understands
- ❑ Defined by hardware design: machine-dependent
- ❑ Made up of 0s and 1s
- ❑ Instruct computers to perform elementary operations
- ❑ Example:

```
00010101000101010100010110000001
10100101011010101010101010101010
00000011111100000011111100000010
```

- ❑ Difficult for humans to read and write

# Assembly Language 汇编语言

- ❑ Example:
  - ❑ Load Basepay
  - ❑ Add Overpay
  - ❑ Store Grosspay
- ❑ English-like abbreviations representing elementary computer operations
- ❑ Easier for humans to read and write
- ❑ Incomprehensible to computers
  - ❑ Translator programs (assemblers): convert to machine language
- ❑ Still quite troublesome to use

# High-level Languages 高级语言

- ❑ Example
  - ❑  $\text{Grosspay} = \text{basepay} + \text{overtimepay}$
  - ❑ More English-like, use common mathematical notations
  - ❑ Single statements accomplish substantial tasks
    - ❑ Assembly language requires many instructions to accomplish simple tasks.
- ❑ Translator programs (Compilers 编译器)
  - ❑ Convert your program to machine language
- ❑ Interpreter programs
  - ❑ Directly execute high-level language programs
- ❑ Different high-level languages: Basic, Pascal, C, Java, C++, etc.

# Basics of a Typical C Environment

## ❑ Phases of C Programs:

### ❑ Edit

### ❑ Compile 编译

- ❑ Preprocess: invoke the processor to deal with the program code by including other files or making some changes (i.e., the use of `#include` or `#define`)

- ❑ Compiler: invoke the compiler to convert the program code to object code.

### ❑ Link 连接

- ❑ Invoke the linker to take one or more object files generated by a compiler and combines them into a single executable file.

### ❑ Execute

- ❑ Preprocess and compiling are commonly performed as one step during compilation.

- ❑ C is a general purpose programming language

- ❑ Small and relatively easy to learn.
